

Abstract

Generating a printstream in a computer that is preferably remote from the one or more inserter systems. Once generated, the printstream is transmitted preferably to a high speed, high volume, printer for producing the printed documents to be included in the mail pieces, such as billing statements. The printed documents are then delivered to the one or more inserter systems, which are to be used as the input sheets in the one or more inserter systems. The print stream is also provided to a workstation computer coupled to the one or more inserter systems. This workstation interpolates the printstream in order to generate a reprint database containing electronic files corresponding to each of the printed documents. Also coupled to the workstation is a local printer, which may be used to generate documents, for re-processing purposes, from data received from the reprint database. The work station also interpolates the printstream in order to generate a job tracking database, which database contains the job level data for the mail pieces that are to be assembled in the one or more inserter systems.
